## I INTRODUCTION

Ionospheric observations are being carried out at the Laboratory of the Military Research and Development Center at Bangkok, Thailand, a joint United States-Thailand organization. A Model C-2 vertical-incidence sounder supplied and operated by the United States Army Radio Propagation Agency has been installed there. Table I gives pertinent information about the site.

Table I  
VERTICAL-INCIDENCE SOUNDER SITE  
AT BANGKOK, THAILAND

Geographic		Geomagnetic	
Latitude	Longitude	Latitude	Longitude
13.73°N	100.57°E	2.5°N	169.83°E

Dip angle: 10°N

Distance from dip equator: 450 km

Equipment:

Instrument: Type C2 (automatic)

PRF: 60 pps

Frequency sweep time: 30 sec

Frequency sweep range: 1 to 25 Mc

Pulse duration: 50  $\mu$ sec

Peak pulse power: approximately 10 kw.

The cooperation and participation of staff members of the Thailand Ministry of Defense and the support of the United States Advanced Research

Project's Agency, the United States Army Electronics Laboratories, and the United States Army Radio Propagation Agency made it possible for the data presented in this report to be accumulated.

## II TERMINOLOGY AND SYMBOLS

The terminology and symbols used in this data report are in accordance with the conventions established by the World Wide Soundings Committee.<sup>1</sup>

### A. TERMINOLOGY

$f_oF_2$ $f_oF_1$ $f_oE$	The ordinary wave critical frequency for the $F_2$ and $F_1$ layers and the E region, respectively.
$f_oE_s$	The ordinary wave top frequency corresponding to the highest frequency at which a mainly continuous $E_s$ trace is observed.
$f_bE_s$	The blanketing frequency of an $E_s$ layer, i.e., the lowest ordinary wave frequency at which the $E_s$ layer begins to become transparent. (This is usually determined from the minimum frequency at which reflections from layers at greater heights are observed.)
$f_{min}$	The frequency below which no echoes are observed.
$M(3000)F_2$	The maximum usable frequency factor for a path of 3000 km for transmission by the $F_2$ layer.
$h'F_2$	The minimum virtual height of the ordinary wave trace for the highest stable stratification in the F region.
$h'F$	The most significant F-region virtual height parameter, that for the lowest F-region stratification. (Thus $h'F$ is identical with the current $h'F_2$ when F-region stratification is absent, i.e., at night, and with current $h'F_1$ when $F_1$ stratification is present.)

<sup>1</sup>W. R. Piggott and K. Rawer, URSI Handbook of Ionogram Interpretation and Reduction of the World Wide Sounding Committee (Elsevier Publishing Company, Amsterdam, London, New York, 1961).

## B. DESCRIPTIVE LETTERS

Certain effects observed on ionograms may make it difficult or impossible to obtain accurate numerical values. The descriptive letters listed below, when used alone indicate, in general, the presence of a phenomenon that may have influenced the measurement. Qualifying letters (Sec. C) indicate the nature of the uncertainty.

- A A lower thin layer present, e.g., E<sub>s</sub>
- B Absorption in the vicinity of  $f_{min}$
- C Any non-ionospheric reason
- D The upper limit of the normal frequency range
- E The lower limit of the normal frequency range
- F Spread echoes present
- G Ionization density of the layer too small for measurement
- H Stratification present
- L No sufficiently definite cusp between layers of the trace
- M Ordinary and extraordinary components indistinguishable
- N Conditions such that the measurement cannot be interpreted
- O Measurement referring to the ordinary component
- R Attenuation in the vicinity of a critical frequency
- S Interference or atmospherics
- T Value determined by a sequence of observations, the actual observation being inconsistent or doubtful
- V Forked trace
- W Echo lying outside the height range recorded
- X Measurement referring to the extraordinary component
- Y Intermittent trace
- Z Third magneto-ionic component present.

## C. QUALIFYING LETTERS

- D Greater than. . .
- E Less than. . .

- I An interpolated value
- J Ordinary component characteristic deduced from the extraordinary component
- O Extraordinary component characteristic deduced from the ordinary component
- T Value determined by a sequence of observations, the actual observation being inconsistent or doubtful
- U Uncertain numerical value
- Z Measurement deduced from the third magneto-ionic component.

#### D. DESCRIPTION OF STANDARD TYPES OF E<sub>s</sub>

The eight standard types of E<sub>s</sub> are identified by lower-case letters: f, l, c, h, q, r, a, and s. These letters suggest the corresponding names flat, low, cusp, high, equatorial, retardation, auroral, and slant, respectively, but are not restrictive. The letter n is used to designate an E<sub>s</sub> trace that does not correspond to one of the eight types. The classifications are:

- f An E<sub>s</sub> trace showing no appreciable increase of height with frequency, usually relatively solid at most latitudes. (This classification may be used only at night; it appears that flat E<sub>s</sub> traces observed in the daytime are classified according to their virtual height: h or l.)
- l A flat E<sub>s</sub> trace at or below the normal E-region minimum virtual height in the day or below the E-region minimum virtual height at night.
- c An E<sub>s</sub> trace showing a relatively symmetrical cusp at or below f<sub>o</sub>E. (This is usually continuous with the normal E trace, although when the deviative absorption is large, part or all of the cusp may be missing—usually a daytime type.)
- h An E<sub>s</sub> trace showing a discontinuity in height with the normal E-region trace at or above f<sub>o</sub>E and an asymmetrical cusp. (The low-frequency end of the E<sub>s</sub> trace lies clearly above the high-frequency end of the normal E trace—usually a daytime type.)
- q An E<sub>s</sub> trace that is diffuse and nonblanketing over a wide frequency range, the spread being most pronounced at the upper edge of the trace. (This type is common in daytime in the vicinity of the magnetic equator.)
- r An E<sub>s</sub> trace that is nonblanketing over part or all of its frequency range, showing an increase in virtual height at the high-frequency

and similar to group retardation. (This is distinguished from the usual group retardation—as in the case of an occulting thick E region—by the lack of group retardation in the F traces at corresponding frequencies and the lack of complete blanketing.)

- a An E<sub>s</sub> pattern having a well-defined flat or gradually rising lower edge with stratified and diffuse (spread) traces present above it. (These sometimes extend over several hundred kilometers of virtual height.)
- s A diffuse E<sub>s</sub> trace that rises steadily with frequency, usually emerging from another type of E<sub>s</sub> trace. (The rising trace alone is classified as s; the horizontal trace is classified separately. At high latitudes, the slant trace usually starts to rise from a horizontal E<sub>s</sub> trace, such as l or f, at frequencies that greatly exceed the E-region critical frequency, e.g., about 6 Mc; whereas at low latitudes it usually rises from equatorial-type E<sub>s</sub>, q, c, or h, at frequencies near the regular E critical frequency. Type s is never used to determine f<sub>o</sub>E unless echoes clearly identifiable as E<sub>s</sub> echoes are seen.)
- n An E trace that cannot be classified as one of the standard types. (This must not be used for intermediate cases between any two classes. A choice should always be made whenever possible, even if it is doubtful.)

#### E. MULTIPLE REFLECTIONS FROM E<sub>s</sub>

When the ionogram shows the presence of multiple reflections from E<sub>s</sub>, the number of traces seen will be recorded with the letter indicating the type.
